The data stream then moves the data to a conditioning loop, which de-noises and filters the data. Then it transfers the data to a storage (RAW) and processing loop. The real-time processing loop runs necessary calculations for cylinder volume, pressure rise rate, heat release rate, start and end of combustion, mean effective pressure, and cycle-to-cycle variation in the background.

Also, the standard ELM327 is employed as a connection adapter to analyze data sets and to calculate the ideal time for hydrogen injection. This process is achieved by an in-situ generator as a supplementary fuel source for internal combustion engines. It permits the reduction of greenhouse gas emissions and improves fuel efficiency, as it has already been reported in multiple previous types of research.

An internal combustion engine (ICE) is a heat engine in which the combustion of a fuel occurs with an oxidizer (usually air) in a combustion chamber that is an integral part of the working fluid flow circuit. In an internal combustion engine, the expansion of the high-temperature and high-pressure gases produced by combustion applies direct force to some component of the engine.
